Abstract: This study presents model architecture of neural network for forecasting the price of share in the share market. Many methods like technical analysis, fundamental analysis, time series analysis and statistical analysis etc are all used to attempt to predict the price in the share market but none of these methods are proved as a consistently acceptable prediction tool. Artificial neural network, a field of artificial intelligence, is a popular way to identify unknown and hidden patterns in data which is suitable for share market prediction. For predicting of share price using artificial neural network, there are two modules, one is training session and other is predicting price based on previously trained data. We used Backpropagation algorithm for training session and multilayer feedforward network as a network model for predicting price. In this paper, we present a method which can forecast share market price using backpropagation algorithm and multilayer feedforward network.

Keywords: Neural Network (NN), Prediction, Artificial Intelligence (AI), Backpropagation (BP), Multilayer Feedforward Network.

1. INTRODUCTION

Computational Intelligence techniques have been used as part of stock trading systems for some time (Atsalakis, G. S., Valavanis, K.P, 2009). Neural networks are among one of the most popular choices. In some studies stock prices were directly used for time series forecasting, but in most cases, technical or fundamental analysis indicators were used as features for the neural network models (Chen, A.S., Leung, M.T., Daouk, H., 2003; Wang, J.Z., Wang, J.J., Zhang, Z.G., Guo, S.P., 2011). Optimizing the neural network that is developed for stock trading (Kwon, Y.K., Moon, B.R., 2007). From the analyses of various statistical models, Artificial Neural Networks are analogous to nonparametric, nonlinear, regression models. So, Artificial Neural Networks (ANN) certainly has the potential to distinguish unknown and hidden patterns in data which can be very effective for share market prediction. If successful, this can be beneficial for investors and financers and that can positively contribute to the economy. There are different methods that have been applied in order to predict Share Market returns. (Tang.Z and Fishwick.P.A, 1993; Wang.J.H and Leu.J.Y.,1996) provided a general introduction of how a neural network should be developed to model financial and economic time series. During the last decade, Artificial Neural Networks have been used in share market prediction. One of the first such projects was by (Kimoto, T., et al., 1990) who had used ANN for the prediction of Tokyo stock exchange index. (Minzuno, H., et al., 1998) applied ANN again to Tokyo stock exchange to predict buying and selling signals with an overall prediction rate of 63%. (Sexton, R.S., et al., 1998) theorized that the use of momentum and start of learning at random points may solve the problems that may occur in training process in 1998. (Phua, P.K.H. Ming, D., Lin, W, 2000) applied neural network with genetic algorithm to the stock exchange market of Singapore and predicted the market direction with an accuracy of 81%. This study presents Back propagation method for training the Neural Network and Multilayer Feed forward network in order to forecast the share market values. The aim of this paper is to use Artificial Neural Networks to forecast Bangladesh Stock Exchange market index values with reasonable a degree of accuracy.

The remain of this paper is organized as follows. A brief literature survey and technical analysis are presented in Section 2. The system of neural network in Section 3. Section 4 presents the proposed forecasting model. Results obtained from ANN modelling and time series modelling are explained in Sections 5. Section 7 concludes the paper.

2. FORECASTING METHOD ANALYSIS

Trading shares and commodities were primarily based on intuitions. As the trading grew, people tried to find methods and tools which can accurately predict the share prices increasing their gains and minimizing their risk. Many methods like fundamental analysis, technical analysis, and machine learning method have all been used to attempt predictions of share prices but none of these methods have been proven as a consistently applicable prediction tool.

2.1. Fundamental Analysis

Fundamental analysis is the physical study of a company in terms of its product sales, manpower, quality, infrastructure etc. to understand it standing in the market and thereby its profitability as an investment (Samarth Agarwal & Manol Jindal, 2010). The fundamental analysts believe that the market is defined 90 percent by logical and 10 percent by physiological factors. But, this analysis is not suitable for our study because the data it uses to determine the intrinsic value of an asset does not change on daily basis and therefore is not suitable for short-term basis. However, this analysis is suitable for predicting the share market only in long-term basis.

2.2. Technical Analysis

The technical analysis predicts the appropriate time to buy or sell a share. Technical analysts use charts which contain technical data like price, volume, highest and lowest prices per trading to predict future share movements. Price charts are used to recognize trends. These trends are understood by supply and demand issues that often have cyclical or some sort of noticeable patterns. To understand a company and its profitability through its share prices in the market, some parameters can guide an investor towards making a careful decision. These parameters are termed Indicators and Oscillators (Rumelhart, D.D., et al., 1991). This is a very popular approach used to predict the market. But the problem of this analysis is that the extraction of trading rules from the study of charts is highly subjective, as a result different analysts extract different trading rules studying the same charts. This analysis can be used to predict the market price on daily basis but we will not use this approach because of its subjective nature.

3. System of Artificial Neural Network

For this kind of chaotic system the neural network approach is suitable because we do not have to

understand the solution. This is a major advantage of neural network approaches. On the other hand in the traditional techniques we must understand the inputs, the algorithms and the outputs in great detail. With the neural network we just need to simply show the correct output for the given inputs. With sufficient amount of training, the network will mimic the function (Stuart Russell, 2004). Another advantage of neural network is that during the tanning process, the network will learn to ignore any inputs that don't contribute to the output (Stuart Russell, 2004).

For proposed system, there is a training phase where some parameters named weights are found from this section and backpropagation algorithm is used for this training phase. These weights are used in forecasting phase using same equations which are used in training phase. This is basic architecture of proposed system and this method is known as a feedforward network. There are a lot of inputs in share market which are impacts in share price. But all the inputs are not used in our system because their impacts are not significant in share market price. We used five inputs for the system. The inputs are: General Index (GI), P/E ratio, Net Asset Value (NAV), Earnings per Share (EPS) and volume. Then, we normalized the data set according to the network and the feed the data to the network.

***** Backpropagation with feedforward NN:

Back-propagation algorithm (Simon Haykin, 1998; Zhang Y.-Q and A. Kandel, 1998) is basically the process of back-propagating the errors from the output layers towards the input layer during training sessions. Back-propagation is necessary because the hidden units have no target values which can be used, so these units must be trained based on errors from the previous layers. The output layer has a target value which is used to compare with calculated value. As the errors are back-propagated through the nodes, the connection weights are continuously updated. Training will occur until the errors in the weights are adequately small to be accepted. On the other hand the computational complexity of back-propagation algorithm is only O (n). These features of the algorithm are the main criteria for predicting share prices accurately.

The main steps using the backpropagation algorithm as follows:

- Step 1: Feed the normalized input data sample, compute the corresponding output;
- Step 2: Compute the error between the output(s) and the actual target(s);
- Step 3: The connection weights and membership functions are adjusted;
- Step 4: If Error > Tolerance Then goto Step 1 Else stop.

4. Structure of Proposed Model

In this section, we used feedforward neural network which has a input layer with five neurons, a hidden layer which has five neurons and a output layer with single neuron. The backpropagation algorithm has been used for training the network.

4.1. Training Phase

There are two phases 1^{st} is the training phase and 2^{nd} is the forecasting phase. The training phase can be divided into two parts, the propagation phase and the weight update phase.

In the propagation phase 1st the input data is normalized for feeding the network into the input nodes using the formula as follows:

$$V' = \frac{V - \min A}{\max A - \min A} (new_{maxA} - new_{minA}) + new_{minA}$$

Where,

V' = Normalized Input.

V = Actual Input.

minA, maxA = Boundary values of the old data range.

new_minA, new_maxA = Boundary values of the new data range. In this case it is -1 and 1 because the backpropagation can only handle data between–one to one (Robert J. Van Eyden, 1996).

Figure 1: Training phase

From Figure 1 we can see that, the normalized input data are fed into the input layer, then the weights are multiplied with the each input data and enter into the neurons of hidden layer, the function of a single neuron are described in the Figure 2, in our model we used single hidden layer. In our model the hidden layer neurons has the same functions as the input layers neurons. After that each neuron passes the output to the next neuron of the output layer. The output layer calculate the in the same way as the hidden layer neuron and generate the final out put which is the compared with the real output and calculate an error signal 'e'.

$$error = \frac{actual output - ANN output}{actual output} *100\%$$

The error 'error' is generated from the propagation phase is used to update the weight using the following formula:

Updated Weight = weight (old) + learning rate * output error * output(neurons i) * output(neurons i+1) * (1 - Output (neurons i+1)).

The above process is done in every weight matrix in the network for updating weight. The Phase 1 and Phase 2 procedure repeatedly used until the sum of square error is zero or close to zero. Like the Figure 2 each neuron is composed of two units. First unit adds products of weights coefficients and input signals (Robert J. Van Eyden, 1996). Then this output enter into the second unit of the neuron which contains the nonlinear activation function, in our model we use sigmoid function as our activation function (W. Duch and N. Jankowski, 2001). The formula of sigmoid activation is: $(x) = \frac{1}{1+e^{-input}}$.

4.2. The forecasting phase

When the neural network is trained then it is ready for forecasting. After training with acceptable error the weights are set into the network then we give the trained network the input data set of the day which price we want to predict. The trained network then predicts the price using the given input data set.

5. RESULTS ANALYSIS AND DISCUSSION

5.1. Input Data

Here is a brief description about the inputs that affect the share price:

✓ General Index (GI): General index is a number that measure the relative value of a section of share market. It reflects the total economic condition of the market. If the general index goes down then it means the economic condition of that particular market is relatively in poor condition.

✓ Net Asset Value (NAV): The Net asset value (NAV) of a company is the company's total assets minus its total liabilities. NAV is typically calculated on a per-share basis.

NAV= (Net asset of a company- Liability)/ Total number of outstanding share.

NAV is also calculated each day by taking the last market value of all securities owned plus all other assets such as cash, subtracting all liabilities and then dividing the result by the total number of shares outstanding.

NAV reflects the financial condition of the company. We can judge the company reputation by the NAV.

Figure 2: A Single Neuron

✓ P/E ratio: The P/E ratio makes a relationship between the share price and the company's earnings. The P/E ratio of a share is a measure of the price paid for a share relative to the annual net income or profit earned by the firm per share.

P/E ratio = Share Price / Earnings Per Share.

If P/E ratio rises then there is a tendency of the company share price falls, the higher P/E ratio then the higher probability to decrease the price.

✓ Earnings per Share (EPS): Earnings per share (EPS) is a comparison tool between two companies. Earnings per share serve as an indicator of a company's profitability.

EPS =Net Earnings / Number of Outstanding Shares.

For output we use the Price of the share. Using this data set we trained the network.

✓ Share Volume: Share volume can be calculated in two different types the daily share volume and the monthly share volume. the total number of share is sold in a particular day is called daily share volume. In monthly share volume is the sum of the trading volumes during that month.

5.2. Results Analysis

Using the developed system to forecast the future stock values with feedforward neural networks we can do some analysis to know the performance of the Back-propagation algorithm. By using the past historical data of ACI pharmaceutical company which include only 2 inputs, we tried to predict stock values for future 8 days of November 2010 from Back-propagation algorithm we are now able to compare the predicted values with the real values. Table 1 and Figure 3 show the forecasting and real values of the ACI pharmaceutical Company. The input past historical

data is from 31-08-2010 to 30-09-2010. The average error of the 1^{st} simulation was 3.71%.

Date	ActualPrice	Predicted Price	Error
01-11-2010	395	401.9	(%) 1.74
02-11-2010	387	401.7	3.79
03-11-2010	392	401.7	2.47
04-11-2010	390	401.7	3.00
08-11-2010	389	401.5	3.21
09-11-2010	385	401.4	4.24
10-11-2010	380	401.5	5.65
11-11-2010	380	401.5	5.65

Figure 3: Graphical representation of Predicting and Actual price of ACI pharmaceutical using two input data sets.

For the second simulation we used the past historical data of ACI pharmaceutical company which include only 5 inputs, we tried to predict stock values for future 8 days of November. Table 2 and Figure 4 show the forecasting and real values of the ACI pharmaceutical Company. The input past historical data is from 1-9-2010 to 31-10-2010. The average error of the 2nd simulation was 1.53 %.

Date	Actual Price	Predicted Price	Error(%)
01-11-2010	395	392.7	0.58
02-11-2010	387	393.3	1.62
03-11-2010	392	392.5	0.12
04-11-2010	390	392.0	0.51
08-11-2010	389	392.8	0.97
09-11-2010	385	392.5	1.94
10-11-2010	380	392.5	3.28
11-11-2010	380	392.3	3.23

(%) of ACI pharmaceutical using five input dataset	Table 2: P	redicting pric	e, Actual price a	and Error
	(%) of ACI	pharmaceutic	cal using five inp	out datasets

The more input data we have the better training and get more close results. This means that, more the available data for predicting financial markets, the greater the chances of an accurate forecast. But the sum squared error was high for the 5 input dataset than the 2 input data sets but the forecasting error was minimal.

5.3. DISCUSSION

- We observed that when we take 2 inputs for forecasting the sum squared error was high. But when we take 4 inputs the sum squared error was minimized. But when we take 5 input then the sum squared error is higher than the 4 input technique.
- When we take the data of share market in a sequential date, we can predict the share price nearer to the actual price. But if we take the data of discontinuous date the difference between the predicted price and actual price was relatively high.
- In the training time if any input changed suddenly at a high rate then the forecasting was not near to the actual price.

Figure 4: Graphical representation of Predicting and Actual price of ACI pharmaceutical using five input datasets.

6. CONCLUSION:

In this paper, a time series forecasting model based artificial neural network is presented to prediction price of share market. With respect to the presented neural network model in this study, we may conclude that by considering the capabilities of artificial neural network in learning, errors can be minimized tangibly. It has been proven already through research in term of share markets. The detail of demonstration was concluded in Tables 1 - 2 and Figures 3 - 4. For future work, we plan on combining more technical parameters and utilize other deep neural network models.
